Circular cone convexity and some inequalities associated with circular cones

Jinchuan Zhou¹, Jein-Shan Chen²* and Hao-Feng Hung²

Abstract

The study of this paper consists of two aspects. One is characterizing the so-called circular cone convexity of \( f \) by exploiting the second-order differentiability of \( f \); the other is introducing the concepts of determinant and trace associated with circular cone and establishing their basic inequalities. These results show the essential role played by the angle \( \theta \), which gives us a new insight when looking into properties about circular cone.

Keywords: circular cone; convexity; determinant; trace

1 Introduction

Recently, much attention has been paid to the nonsymmetric cone optimization problems, see [1–4] and the references therein. Unlike symmetric cones [5], there is no unified structure for nonsymmetric cones. Hence, how to tackle nonsymmetric cone optimization is still an issue. For symmetric cone optimization, the algebraic structure associated with symmetric cones, including second-order cone and positive semi-definite matrix cones, allows us to study them via exploiting the unified Euclidean Jordan algebra [5]. In general, the way to deal with nonsymmetric cone optimization depends on the feature of the associated nonsymmetric cone. In this paper, we focus on a special nonsymmetric cone, circular cone \( \mathcal{L}_\theta \). The circular cone [6–9] is a pointed closed convex cone having hyperspherical sections orthogonal to its axis of revolution about which the cone is invariant to rotation. Let its half-aperture angle be \( \theta \) with \( \theta \in (0, 90^\circ) \). Then, it is mathematically expressed as

\[
\mathcal{L}_\theta := \left\{ x = (x_1, x_2)^T \in \mathbb{R} \times \mathbb{R}^{n-1} \mid x_1 \geq \|x\| \cos \theta \right\}
\]

\[
= \left\{ x = (x_1, x_2)^T \in \mathbb{R} \times \mathbb{R}^{n-1} \mid x_1 \geq \|x_2\| \cot \theta \right\}.
\]

Real applications of a circular cone lie in some engineering problems, for example, in the formulation for optimal grasping manipulation for multi-fingered robots, the grasping force of \( i \)th finger is subject to a circular cone constraint, see [10, 11] and references for more details.

Although \( \mathcal{L}_\theta \) is a nonsymmetric cone, we can, due to its special structure, establish the explicit form of orthogonal decomposition (or spectral decomposition) [7] as

\[
x = \lambda_1(x) \cdot u_x^{(1)} + \lambda_2(x) \cdot u_x^{(2)},
\]

(1)
where
\[
\begin{align*}
\lambda_1(x) &= x_1 - \|x_2\| \cot \theta, \\
\lambda_2(x) &= x_1 + \|x_2\| \tan \theta
\end{align*}
\]
and
\[
\begin{align*}
\lambda_u^{(1)}(x) &= \frac{1}{\sin^2 \theta} \begin{bmatrix} 1 & 0 \\ 0 & \cot \theta \lambda_{u-1} \end{bmatrix} \begin{bmatrix} 1 \\ -x_2 \end{bmatrix} = \begin{bmatrix} \sin^2 \theta \\ -\sin \theta \cos \theta \bar{\lambda}_2 \end{bmatrix}, \\
\lambda_u^{(2)}(x) &= \frac{1}{\tan^2 \theta} \begin{bmatrix} 1 & 0 \\ 0 & \tan \theta \lambda_{u-1} \end{bmatrix} \begin{bmatrix} 1 \\ x_2 \end{bmatrix} = \begin{bmatrix} \cos^2 \theta \\ \cos \theta \sin \theta \bar{\lambda}_2 \end{bmatrix}
\end{align*}
\]
with \(\bar{x}_2 = x_2/\|x_2\|\) if \(x_2 \neq 0\), and \(\bar{x}_2\) being any vector \(w\) in \(\mathbb{R}^{n-1}\) satisfying \(\|w\| = 1\) if \(x_2 = 0\). Clearly, \(x \in \mathcal{L}_\theta\) if and only if \(\lambda_1(x) \geq 0\).

The formula (1) allows us to define the following vector-valued function:
\[
\tilde{f}^{\mathcal{L}_\theta}(x) := f(\lambda_1(x))\lambda_u^{(1)}(x) + f(\lambda_2(x))\lambda_u^{(2)}(x),
\]
where \(f\) is a real-valued function from \(J\) to \(\mathbb{R}\) with \(J\) being a subset in \(\mathbb{R}\). Let \(S\) be the set of all \(x \in \mathbb{R}^n\) whose spectral values \(\lambda_i(x)\) for \(i = 1, 2\) belong to \(J\), i.e., \(S := \{x \in \mathbb{R}^n \mid \lambda_i(x) \in J, i = 1, 2\}\). According to [12], we know that \(S\) is open if and only if \(J\) is open. In addition, as \(J\) is an interval, then \(S\) is convex because
\[
\min \{\lambda_1(x), \lambda_1(y)\} \leq \lambda_1(\beta x + (1-\beta)y) \leq \lambda_2(\beta x + (1-\beta)y) \\
\leq \max \{\lambda_2(x), \lambda_2(y)\}, \quad \forall \beta \in [0, 1].
\]

Throughout this paper, we always assume that \(J\) is an interval in \(\mathbb{R}\). Clearly, as \(\theta = 45^\circ\), \(\mathcal{L}_{45^\circ}\) reduces to the second-order cone and the above expressions (1) and (2) correspond to the spectral decomposition and the SOC-function associated with the second-order cone, respectively (see [13, 14] for more information regarding \(f^{soc}\)).

It is well known that in dealing with symmetric cone optimization problems, such as second-order cone optimization problems and positive semi-definite optimization problems, this type of vector-valued functions plays an essential role. Inspired by this, we study the properties of \(\tilde{f}^{\mathcal{L}_\theta}\), which is crucial for circular cone optimization problems. In our previous works, we have studied the smooth and nonsmooth analysis of \(\tilde{f}^{\mathcal{L}_\theta}\) [8, 10]; and the circular cone monotonicity and second-order differentiability of \(\tilde{f}^{\mathcal{L}_\theta}\) [9]. From the aforementioned research, there is an interesting observation: some properties commonly shared by \(f^{soc}\) and \(f^{\mathcal{L}_\theta}\) are independent of the angle \(\theta\); for example, \(f^{\mathcal{L}_\theta}\) is directionally differentiable, Fréchet differentiable, semi-smooth if and only if \(f\) is directionally differentiable, Fréchet differentiable, semi-smooth; while some properties are dependent on the angle \(\theta\); for example, \(f^{\mathcal{L}_\theta}\) with \(f(t) = -1/t\) for \(t > 0\) is circular cone monotone as \(\theta \in [45^\circ, 90^\circ)\), but not circular cone monotone as \(\theta \in (0, 45^\circ)\).

In this paper, we further study the circular cone convexity of \(f\). More precisely, a real-valued function \(f: J \to \mathbb{R}\) is said to be \(\mathcal{L}_{\theta}\)-convex of order \(n\) on \(S\) if for any \(x, y \in S\),
\[
f^{\mathcal{L}_\theta}(\beta x + (1-\beta)y) \leq \mathcal{L}_{\theta} \beta f^{\mathcal{L}_\theta}(x) + (1-\beta) f^{\mathcal{L}_\theta}(y), \quad \forall \beta \in [0, 1].
\]
The characterization of $\mathcal{L}_\theta$-convexity is based on the observation that $f$ is $\mathcal{L}_\theta$-convex if and only if $(f^{(n)})''(x)(h, h) \in \mathcal{L}_\theta$ for all $h \in \mathbb{R}^n$. Our result shows that the circular cone convexity requires that the angle $\theta$ belongs in $[45^\circ, 90^\circ)$. In particular, we show that $f$ is $\mathcal{L}_\theta$-convex of order 2 if and only if $\theta \in [45^\circ, 90^\circ)$ and $f$ is convex.

On the other hand, using the spectral decomposition (1), we define the determinant and trace of $x$ in the framework of circular cone as

$$\det(x) := \lambda_1(x)\lambda_2(x) \quad \text{and} \quad \tr(x) := \lambda_1(x) + \lambda_2(x),$$

respectively. In the symmetric cone setting, the concepts of determinant and trace are the key ingredients of barrier and penalty functions which are used in barrier and penalty methods (including interior point methods) for symmetric cone optimization, see [15–17]. Here we further study some basic inequalities of $\det(x)$ and $\tr(x)$ in the framework of circular cone. As seen in Section 3, the obtained inequalities are classified into three categories: (i) the first class is independent of the angle (i.e., still holds in the framework of circular cone); (ii) the second class is dependent on the angle, for example, for $x, y \in \mathcal{L}_\theta$, the inequality

$$\det(e + x + y) \leq \det(e + x)\det(e + y),$$

where $e = (1, 0, \ldots, 0) \in \mathbb{R}^n$, fails as $\theta \in (0, 45^\circ)$ but holds as $\theta \in [45^\circ, 90^\circ)$; (iii) the third class always fails no matter what value of $\theta$ is chosen. These results give us a new insight into a circular cone and make us focus more on the role played by the angle $\theta$.

The notation used in this paper is standard. For example, denote by $\mathbb{R}^n$ the $n$-dimensional Euclidean space and by $\mathbb{R}_+$ the set of all nonnegative real scalars, i.e., $\mathbb{R}_+ = \{t \in \mathbb{R} \mid t \geq 0\}$. For $x, y \in \mathbb{R}^n$, the inner product is denoted by $x^Ty$. Let $\mathbb{S}^n$ mean the spaces of all real symmetric matrices in $\mathbb{R}^{n \times n}$, and let $\mathbb{S}^+_n$ denote the cone of positive semi-definite matrices. We write $x \succeq_L y$ to stand for $x - y \in \mathcal{L}_\theta$. Finally, we define $0 \succeq_L 0 := 0$ for convenience.

2 Circular cone convexity

The main purpose of this section is to provide characterizations of $\mathcal{L}_\theta$-convex functions. First, we need the following technical lemma.

**Lemma 2.1** Given $\alpha_i \in \mathbb{R}$ for $i = 1, \ldots, 6$ and $\beta_i \in \mathbb{R}$ for $i = 1, 2, 3$, we define

$$\mathcal{F}(\beta_1, \beta_2, \beta_3) := \alpha_1\beta_1^4 + \alpha_2\beta_2^4 + \alpha_3\beta_1^2\beta_3^2 + \alpha_4\beta_2^2\beta_3^2 + \alpha_5\beta_1\beta_2\beta_3^2 + \alpha_6\beta_1\beta_2\beta_3^2. \tag{3}$$

If $\mathcal{F}(\beta_1, \beta_2, \beta_3) \geq 0$ for all $(\beta_1, \beta_2, \beta_3) \in \mathbb{R}^3$, then

$$\alpha_1 \geq 0, \quad \alpha_2 \geq 0, \quad \alpha_4 \geq 0, \quad \alpha_5 \geq 0, \quad \alpha_3 \geq -2\sqrt{\alpha_1\alpha_2}. \tag{4}$$

Furthermore, if

$$\alpha_3^2 \leq \begin{cases} 4\alpha_2\alpha_5 & \text{for } \alpha_3 \geq 0, \\ 4[\alpha_2 - (\alpha_2^2/4\alpha_1)]\alpha_5 & \text{for } \alpha_3 \in [-2\sqrt{\alpha_1\alpha_2}, 0), \end{cases} \tag{4}$$

then $\mathcal{F}(\beta_1, \beta_2, \beta_3) \geq 0$ for all $(\beta_1, \beta_2, \beta_3) \in \mathbb{R}^3$. 
Proof If $\beta_1 = 0$, then $\mathcal{F}(\beta_1, \beta_2, \beta_3) = \beta_2^2 (\alpha_2 \beta_3^2 + \alpha_4 \beta_3^2)$. From $\mathcal{F}(\beta_1, \beta_2, \beta_3) \geq 0$, we have $\alpha_2 \beta_3^2 + \alpha_4 \beta_3^2 \geq 0$. Thus, $\alpha_2 \geq 0$ by letting $\beta_2 \to 0$ and $\alpha_4 \geq 0$ by letting $\beta_3 \to 0$.

If $\beta_2 = 0$, then $\mathcal{F}(\beta_1, \beta_2, \beta_3) = \beta_3^2 (\alpha_1 \beta_1^2 + \alpha_3 \beta_3^2)$. From $\mathcal{F}(\beta_1, \beta_2, \beta_3) \geq 0$, we obtain $\alpha_1 \geq 0$ and $\alpha_2 \geq 0$.

If $\beta_2 = 0$, then

$$\mathcal{F}(\beta_1, \beta_2, \beta_3) = \alpha_1 \beta_1^4 + \alpha_2 \beta_3^4 + \alpha_3 \beta_3^2 \beta_1^2 = \beta_1^2 \beta_3 \alpha_1 \left( \frac{\beta_1}{\beta_3} \right)^2 + \alpha_2 + \alpha_3 \left( \frac{\beta_3}{\beta_1} \right)^2 \quad (5)$$

whenever $\beta_1 \neq 0$ and $\beta_3 \neq 0$. Let $t = \beta_1/\beta_3$. From $\mathcal{F}(\beta_1, \beta_2, \beta_3) \geq 0$, equation (5) implies

$$\alpha_3 \geq -\alpha_1 t^2 - \alpha_2 (1/t^2), \quad \forall t \neq 0,$$

i.e.,

$$\alpha_3 \geq \max_{t \neq 0} \left[-\alpha_1 t^2 - \alpha_2 (1/t^2)\right] = -\min_{t \neq 0} \left[\alpha_1 t^2 + \alpha_2 (1/t^2)\right] = -2\sqrt{\alpha_1 \alpha_2}.$$

Furthermore, if $\alpha_3 \geq 0$, then

$$\mathcal{F}(\beta_1, \beta_2, \beta_3) \geq \alpha_3 \beta_3^4 + \alpha_5 \beta_1^2 \beta_3^2 + \alpha_6 \beta_1 \beta_2 \beta_3^2 = \beta_3^2 \beta_1 \beta_2 \left[ \frac{\alpha_2}{\alpha_6/2} \frac{\alpha_6/2}{\alpha_5} \right] \geq 0,$$

where the last step is due to

$$\begin{bmatrix} \alpha_2 & \alpha_6/2 \\ \alpha_6/2 & \alpha_5 \end{bmatrix} \succeq 0,$$

which is ensured by condition (4). Similarly, if $\alpha_3 \in [-2\sqrt{\alpha_1 \alpha_2}, 0]$ (implying $\alpha_1 \neq 0$ in this case), then

$$\mathcal{F}(\beta_1, \beta_2, \beta_3)$$

$$= \left( \sqrt{\alpha_1} \beta_1^2 + \frac{\alpha_3}{2\sqrt{\alpha_1}} \beta_3^2 \right)^2 + \left( \alpha_2 - \frac{\alpha_3^2}{4\alpha_1} \right) \beta_1^4 + \alpha_4 \beta_3^2 \beta_1^2 + \alpha_5 \beta_1^2 \beta_3^2 + \alpha_6 \beta_1 \beta_2 \beta_3^2$$

$$\geq \left( \alpha_2 - \frac{\alpha_3^2}{4\alpha_1} \right) \beta_1^4 + \alpha_5 \beta_1^2 \beta_3^2 + \alpha_6 \beta_1 \beta_2 \beta_3^2$$

$$= \left[ \beta_1 \beta_2 \right] \begin{bmatrix} \alpha_2 - \alpha_3^2/4\alpha_1 & \alpha_6/2 \\ \alpha_6/2 & \alpha_5 \end{bmatrix} \left[ \beta_1 \beta_2 \right] \geq 0,$$

where the last step is due to

$$\begin{bmatrix} \alpha_2 - \alpha_3^2/4\alpha_1 & \alpha_6/2 \\ \alpha_6/2 & \alpha_5 \end{bmatrix} \succeq 0,$$

which is ensured by condition (4) and the fact $\alpha_2 - \alpha_3^2/4\alpha_1 \geq 0$ since $-2\sqrt{\alpha_1 \alpha_2} \leq \alpha_3 < 0$.

This completes the proof. \hfill \Box

Lemma 2.2 [9, Theorem 3.1] Let $f : I \to \mathbb{R}$ and $f^{(2)}$ be defined as in (2). Then $f^{(2)}$ is second-order differentiable at $x \in S$ if and only if $f$ is second-order differentiable at $\lambda_i(x) \in I$ for
\( i = 1, 2. \) Moreover, for \( u, v \in \mathbb{R}^n \), if \( x_2 = 0 \), then
\[
(f^{L_0})''(x)(u, v) = \begin{cases} f''(x_1) \left[ \frac{u^T v}{u_1 v_2 + v_1 u_2} \right], & \text{either } u_2 = 0 \text{ or } v_2 = 0, \\ \left[ f''(x_1)(u_1 v_2 + v_1 u_2) + \frac{1}{2} f'''(x_1)(\tan \theta - \cot \theta) \|v_2 + \bar{a}_2 v_2\| v_2 \|u_2\| \right], & \text{otherwise}. \end{cases}
\]

If \( x_2 \neq 0 \), then
\[
(f^{L_0})''(x)(u, v) = \begin{bmatrix} I_1 \\ I_2 \end{bmatrix},
\]
where
\[
I_1 := v_1 u_1 \bar{x} + \bar{\vartheta}(u_1 \bar{x}_2 + v_1 \bar{x}_2 u_2) + \bar{a} v^T u_2 + (\bar{\eta} - \bar{a}) x^T_2 v_2 \bar{x}_2 u_2,
\]
\[
I_2 := \left[ (\bar{\eta} - \bar{a}) u_1 \bar{x}_2 + (\bar{\sigma} - 3 \bar{a}) x^T_2 x_2 \bar{x}_2 u_2 + \bar{\vartheta} v_1 u_1 + (\bar{\eta} - \bar{a}) v_1 \bar{x}_2 u_2 \right] \bar{x}_2
\]
\[
+ \bar{a} \left[ x^T_2 u_2 v_2 + v^T_2 u_2 \bar{x}_2 + \bar{x}^T_2 v_2 u_2 \right] + \bar{a} (u_1 v_2 + v_1 u_2)
\]
with
\[
\bar{a} = \frac{f'(\lambda_2(x)) - f'(\lambda_1(x))}{\lambda_2(x) - \lambda_1(x)},
\]
\[
\bar{\vartheta} = \frac{\tan \theta}{1 + \cot^2 \theta} f''(\lambda_1(x)) + \frac{\tan \theta}{1 + \tan^2 \theta} f''(\lambda_2(x)),
\]
\[
\bar{\eta} = \frac{\cot \theta}{1 + \cot^2 \theta} f''(\lambda_1(x)) + \frac{\tan^2 \theta}{1 + \tan^2 \theta} f''(\lambda_2(x)),
\]
\[
\bar{\varphi} = \frac{1}{\|x_2\|} \left[ \frac{\cot^2 \theta}{1 + \cot^2 \theta} f''(\lambda_1(x)) + \frac{\tan^2 \theta}{1 + \tan^2 \theta} f''(\lambda_2(x)) - \frac{f(\lambda_2(x)) - f(\lambda_1(x))}{\lambda_2(x) - \lambda_1(x)} \right],
\]
\[
\bar{\sigma} = \frac{\cot^3 \theta}{1 + \cot^2 \theta} f'''(\lambda_1(x)) + \frac{\tan^3 \theta}{1 + \tan^2 \theta} f'''(\lambda_2(x)).
\]

The characterization of \( L_0 \)-convexity is established below, which can be regarded as the extension of some results given in [12, 18–20] from the second-order cone setting to the circular cone setting.

**Theorem 2.1** Suppose that \( f : J \to \mathbb{R} \) is second-order continuously differentiable. If \( f \) is \( L_0 \)-convex of order \( n \) on \( S \), then \( \tan \theta \geq 1, f \) is convex on \( J \), and for all \( r_1, r_2 \in J \) with \( r_1 \leq r_2 \),
\[
f''(r_2) \delta(r_2, r_1) + \frac{2}{(r_2 - r_1)^2} \delta(r_1, r_2)^2 \geq \frac{2}{(r_2 - r_1)^2} \delta(r_1, r_2)^2 \tag{6}
\]
and
\[
\left[ \tan^2 \theta \delta(r_1, r_2) + (\tan^2 \theta - 1) \delta(r_2, r_1) \right] f''(r_1) - \frac{2}{(r_2 - r_1)^2} \delta(r_1, r_2) \delta(r_2, r_1)^2 \geq -f''(r_1) \sqrt{\left[ \tan^2 \theta - 1 \right] \delta(r_1, r_2) \left[ 2 \tan^2 \theta \delta(r_1, r_2) + (\tan^2 \theta - 1) \delta(r_1, r_2) \right]}.
\]
\[
\tag{7}
\]
Furthermore, if
\[
\left[ \tan^2 \theta \delta(x_1, x_2) + (\tan^2 \theta - 1)\delta(x_2, x_1) \right] f''(x_1) \geq \frac{2}{(x_2 - x_1)^2} \delta(x_2, x_1)^2
\]  
(8)

and
\[
8\delta(x_2, x_1)\delta(x_1, x_2)^2 \leq \left[ 2 \tan^2 \theta \delta(x_1, x_2) + (\tan^2 \theta - 1)\delta(x_2, x_1) \right] f''(x_1)f''(x_2)(x_2 - x_1)^4, 
\]
(9)
or if
\[
\left[ \tan^2 \theta \delta(x_1, x_2) + (\tan^2 \theta - 1)\delta(x_2, x_1) \right] f''(x_1) < \frac{2}{(x_2 - x_1)^2} \delta(x_2, x_1)^2
\]

and
\[
8\delta(x_2, x_1)^2\delta(x_1, x_2)^2(\tan^2 \theta - 1)f''(x_1)
\]
\[
\leq \left\{ \left( \tan^2 \theta - 1 \right) f''(x_1)^2 \left[ 2 \tan^2 \theta \delta(x_1, x_2) + (\tan^2 \theta - 1)\delta(x_2, x_1) \right] \delta(x_2, x_1) \right\}
\]
\[
- \left[ (\tan^2 \theta \delta(x_1, x_2) + (\tan^2 \theta - 1)\delta(x_2, x_1)) f''(x_1) - \frac{2}{(x_2 - x_1)^2} \delta(x_2, x_1)^2 \right]^2
\]
\[
\times f''(x_2)(x_2 - x_1)^4, 
\]
(10)
then \( f \) is \( \mathcal{L}_\theta \)-convex. Here \( \delta(\tau, \tau') := f(\tau) - f(\tau') - f'(\tau)(\tau - \tau') \) for \( \tau, \tau' \in J \).

**Proof** According to [9, Theorem 3.2], \( f \) is \( \mathcal{L}_\theta \)-convex if and only if \( (f^{\mathcal{L}_\theta}')(x)(h, h) \in \mathcal{L}_\theta \) for all \( x \in S \) and \( h \in \mathbb{R}^n \). We proceed the proof by considering the following three cases.

Case 1. For \( x_2 = 0 \) and \( h_2 = 0 \), it follows from Lemma 2.2 that
\[
(f^{\mathcal{L}_\theta})^\circ(x)(h, h) = f''(x_1) \begin{bmatrix} h_1^2 \\ 0 \end{bmatrix}.
\]
Hence, \( (f^{\mathcal{L}_\theta})^\circ(x)(h, h) \in \mathcal{L}_\theta \) if and only if \( f''(x_1) \geq 0 \).

Case 2. For \( x_2 = 0 \) and \( h_2 \neq 0 \), it follows from Lemma 2.2 that
\[
(f^{\mathcal{L}_\theta})^\circ(x)(h, h) = \begin{bmatrix} f''(x_1) \|h\|^2 \\ 2f''(x_1)h_1h_2 + f''(x_1)(\tan \theta - \cot \theta)\|h_2\| \|h_2\| \end{bmatrix}.
\]
Hence, \( (f^{\mathcal{L}_\theta})^\circ(x)(h, h) \in \mathcal{L}_\theta \) if and only if \( f''(x_1) \geq 0 \) and
\[
\tan \theta \|h\|^2 \geq \left[ 2h_1 + (\tan \theta - \cot \theta)\|h_2\| \|h_2\| \right],
\]
i.e.,
\[
-\tan \theta \left( h_1^2 + |h_2|^2 \right) \leq \left[ 2h_1 + (\tan \theta - \cot \theta)\|h_2\| \|h_2\| \right]h_2 \leq \tan \theta \left( h_1^2 + |h_2|^2 \right).
\]
Dividing by $\|h_2\|^2$ and letting $t = h_1/\|h_2\|$ yields

$$-\tan \theta (t^2 + 1) \leq 2t + \tan \theta - \cot \theta \leq \tan \theta (t^2 + 1)$$

$$\iff \max_{t \in \mathbb{R}} -\tan \theta (t^2 + 1) - 2t \leq \tan \theta - \cot \theta \leq \min_{t \in \mathbb{R}} \tan \theta (t^2 + 1) - 2t$$

$$\iff \cot \theta - \tan \theta \leq \tan \theta - \cot \theta \leq \tan \theta - \cot \theta$$

$$\iff \tan \theta \geq 1.$$

**Case 3.** For $x_2 \neq 0$, due to the simplification of notation, let us denote

$$\mu_1 := h_1 - \cot \theta \bar{x}_x h_2, \quad \mu_2 := h_1 + \tan \theta \bar{x}_{\bar{x}} h_2, \quad \mu_3 := \sqrt{\|h_2\|^2 - (\bar{x}_x h_2)^2}.$$  \hfill (11)

Then

$$\bar{x}_x h_2 = \frac{\mu_2 - \mu_1}{\tan \theta + \cot \theta} \quad \text{and} \quad h_1 = \frac{\tan \theta \mu_1 + \cot \theta \mu_2}{\tan \theta + \cot \theta}. \hfill (12)$$

Note that $\mu_1$, $\mu_2$, and $\mu_3$ can take any value in $\mathbb{R} \times \mathbb{R} \times \mathbb{R}_+$ by taking a suitable value of $h$ (because the vector $h$ has $n$ variables). It follows from Lemma 2.2 that

$$(f^{\mathcal{L}_0})''(x)(h, h)$$

$$= \left[ \begin{array}{c} \xi h_1^2 + 2 \tilde{\alpha} \bar{x}_x h_2 h_1 + \bar{\alpha} \|h_2\|^2 + (\bar{\eta} - \tilde{\alpha}) (\bar{x}_x h_2)^2 \\ [\sigma - 3 \tilde{\alpha} (\bar{x}_x h_2)^2 + 2 (\bar{\eta} - \tilde{\alpha}) \bar{x}_x h_2 h_1] \bar{x}_x + [\tilde{\alpha} h_1^2 + \bar{\alpha} \|h_2\|^2] \bar{x}_x + 2 [\bar{\alpha} h_1 + \tilde{\alpha} \bar{x}_x h_2] h_2 \end{array} \right]$$

$$\Theta_1 = \Theta_2 \bar{x}_x + \Theta_3 h_2,$$

where

$$\Theta_1 = \xi h_1^2 + 2 \tilde{\alpha} \bar{x}_x h_2 h_1 + \bar{\alpha} \|h_2\|^2 + (\bar{\eta} - \tilde{\alpha}) (\bar{x}_x h_2)^2,$$

$$\Theta_2 = [\sigma - 3 \tilde{\alpha} (\bar{x}_x h_2)^2 + 2 (\bar{\eta} - \tilde{\alpha}) \bar{x}_x h_2 h_1 + \tilde{\alpha} h_1^2 + \bar{\alpha} \|h_2\|^2],$$

$$\Theta_3 = 2 [\bar{\alpha} h_1 + \tilde{\alpha} \bar{x}_x h_2].$$

Hence, $(f^{\mathcal{L}_0})''(x)(h, h) \in \mathcal{L}_0$ is equivalent to

$$\Theta_1 \geq 0 \quad \text{and} \quad \Theta_2 \tan^2 \theta \geq \|\Theta_2 \bar{x}_x + \Theta_3 h_2\|^2.$$

Note that

$$\Theta_1 = \frac{1}{1 + \cot^2 \theta} f''(\lambda_1(x)) [h_1^2 - 2 (\bar{x}_x h_2) h_1 \cot \theta + (\bar{x}_x h_2)^2 \cot^2 \theta]$$

$$+ \frac{1}{1 + \tan^2 \theta} f''(\lambda_2(x)) [h_1^2 + 2 (\bar{x}_x h_2) h_1 \tan \theta + (\bar{x}_x h_2)^2 \tan^2 \theta]$$

$$+ \tilde{\alpha} \|h_2\|^2 - (\bar{x}_x h_2)^2]$$

$$= \frac{1}{1 + \cot^2 \theta} f''(\lambda_1(x)) \mu_1^2 + \frac{1}{1 + \tan^2 \theta} f''(\lambda_2(x)) \mu_2^2 + \tilde{\alpha} \mu_3^2. \hfill (13)$$
We now claim that Θ₁ ≥ 0 for all \( h \in \mathbb{R}^n \) if and only if

\[
f''(\lambda_1(x)) ≥ 0, \quad f''(\lambda_2(x)) ≥ 0, \quad \text{and} \quad \tilde{a} ≥ 0.
\]  
(14)

The sufficiency is clear. Let us show the necessity. In particular, choosing \( h = (−\tan \theta, \bar{x}_2) \) yields \( \mu_2 = 0 \) and \( \mu_3 = 0 \). It then follows from \( \Theta_1 ≥ 0 \) that \( f''(\lambda_1(x)) ≥ 0 \). If we choose \( h = (\cot \theta, \bar{x}_2) \), then we have \( f''(\lambda_2(x)) ≥ 0 \). Finally, choosing \( h = (1, \bar{x}_2) \) with \( k \in \mathbb{R}, \| \bar{x}_2 \| = 1 \) and \( \tilde{z}_2^T \bar{x}_2 = 0 \) gives

\[
\Theta_1 = \frac{f''(\lambda_1(x))}{1 + \cot^2 \theta} + \frac{f''(\lambda_2(x))}{1 + \tan^2 \theta} + \tilde{a}k^2 ≥ 0.
\]

Dividing by \( k^2 \) both sides and taking the limits as \( k \to \infty \), we obtain \( \tilde{a} ≥ 0 \). Since \( \lambda_i(x) \) can take an arbitrary value in \( J \), it is clear that (14) is equivalent to saying that \( f''(r) ≥ 0 \) for all \( r \in J \), i.e., \( f \) is convex on \( J \). Indeed, the condition \( \tilde{a} ≥ 0 \) is ensured by the fact that \( \tilde{a} = \frac{f''(\lambda_2(x)−f''(\lambda_1(x))}{\lambda_2(\lambda_1(\bar{x}_2))} = f''(t_0) ≥ 0 \) for some \( t_0 \in (\lambda_1(x), \lambda_2(x)) \).

Now we calculate the values of \( \Theta_2 \) and \( \Theta_3 \), respectively.

\[
\Theta_2 = \frac{\cot \theta}{1 + \cot^2 \theta} + \frac{\tan \theta}{1 + \tan^2 \theta} f''(\lambda_2(x))\mu_2^2 + 2(\tilde{d} \mu_2^2 - 2(\tilde{d} \tilde{a} h_2 + \tilde{a} h_1)(\tilde{z}_2^T h_2)
\]

\[
= \frac{\cot \theta}{1 + \cot^2 \theta} f''(\lambda_1(x))\mu_1^2 + \frac{\tan \theta}{1 + \tan^2 \theta} f''(\lambda_2(x))\mu_2^2 + \tilde{d} \mu_2^2 - (\tilde{a} \tilde{z}_2^T h_2) \mu_3 \Theta_3.
\]  
(15)

Meanwhile, it follows from (12) that

\[
\Theta_3 = 2\left( \frac{\mu_1(\tilde{a} \tan \theta - \tilde{d}) + \mu_2(\tilde{a} \cot \theta + \tilde{d})}{\mu_1 \tan \theta + \cot \theta} \right)
\]

\[
= \frac{2}{\tan \theta + \cot \theta} \left( \mu_1(\tilde{a} \tan \theta - \tilde{d}) + \mu_2(\tilde{a} \cot \theta + \tilde{d}) \right).
\]  
(16)

Note that

\[
\| \Theta_2 \tilde{x}_2 + \Theta_3 h_2 \|^2 = \Theta_2^2 + 2\Theta_2 \Theta_3 \tilde{x}_2^T h_2 + \Theta_3^2 \| h_2 \|^2
\]

\[
= \Theta_2^2 + 2\Theta_2 \Theta_3 \tilde{x}_2^T h_2 + \Theta_3^2 [\mu_3^2 + (\tilde{z}_2^T h_2)^2]
\]

\[
= (\Theta_2 + \Theta_3 \tilde{x}_2^T h_2)^2 + \Theta_3^2 \mu_3^2.
\]  
(17)

Putting (13) and (15)-(17) together, the condition \( \Theta_1^2 \tan^2 \theta ≥ \| \Theta_2 \tilde{x}_2 + \Theta_3 h_2 \|^2 \) can be rewritten equivalently as

\[
\tan^2 \theta \left[ \frac{f''(\lambda_1(x))}{1 + \cot^2 \theta} \mu_1^2 + \frac{f''(\lambda_2(x))}{1 + \tan^2 \theta} \mu_2^2 + \tilde{a} \mu_3^2 \right]^2
\]

\[
≥ \left[ -\frac{\cot \theta}{1 + \cot^2 \theta} f''(\lambda_1(x))\mu_1^2 + \frac{\tan \theta}{1 + \tan^2 \theta} f''(\lambda_2(x))\mu_2^2 + \tilde{d} \mu_3^2 \right]^2
\]

\[
+ \frac{4}{(\tan \theta + \cot \theta)^2} \left[ \mu_1(\tilde{a} \tan \theta - \tilde{d}) + \mu_2(\tilde{a} \cot \theta + \tilde{d}) \right]^2 \mu_3^2,
\]
\[ (\tan^4 \theta - 1) f''(\lambda_1(x))^2 \mu_1^3 + (\tan \theta + \cot \theta)^2 (\tilde{a}^2 \tan^2 \theta - \tilde{d}^2) \mu_3^2 \]
\[ + 2 \left[ (\tan \theta + \cot \theta) (\tilde{a} \tan^3 \theta + \tilde{d}) f''(\lambda_1(x)) - 2 (\tilde{a} \tan \theta - \tilde{d}) \right] \mu_1^3 \mu_2^3 \]
\[ + 2 \left[ (\tan \theta + \cot \theta) (\tilde{a} \tan \theta - \tilde{d} f''(\lambda_2(x)) - 2 (\tilde{a} \cot \theta + \tilde{d})^2 \right] \mu_2^4 \mu_3^2 \]
\[ + 2 (\tan^2 \theta + 1) f''(\lambda_1(x)) f''(\lambda_2(x)) \mu_1^3 \mu_2^2 \]
\[ - 8 (\tilde{a} \tan \theta - \tilde{d}) (\tilde{a} \cot \theta + \tilde{d}) \mu_1 \mu_2 \mu_3^2 \geq 0. \quad (18) \]

To apply Lemma 2.1, we need to compute each coefficient in (18). By calculation, we have

\[ \tilde{a} \tan \theta - \tilde{d} \]
\[ = \frac{f'(\lambda_2(x)) - f'(\lambda_1(x))}{\lambda_2(x) - \lambda_1(x)} \tan \theta - 1 \frac{1}{\|x_2\|} \left[ \frac{\cot^2 \theta}{1 + \cot^2 \theta} f'(\lambda_1(x)) + \tan \theta f'(\lambda_2(x)) \right] \]
\[ + \frac{1}{\|x_2\|} \frac{f(\lambda_2(x)) - f(\lambda_1(x))}{\lambda_2(x) - \lambda_1(x)} \]
\[ = \frac{f'(\lambda_2(x)) - f'(\lambda_1(x))}{\lambda_2(x) - \lambda_1(x)} \tan \theta - 1 \frac{1}{\|x_2\|} \left[ \frac{\cot \theta}{\tan \theta + \cot \theta} f'(\lambda_1(x)) + \tan \theta f'(\lambda_2(x)) \right] \]
\[ + \frac{1}{\|x_2\|} \frac{f(\lambda_2(x)) - f(\lambda_1(x))}{\lambda_2(x) - \lambda_1(x)} \]
\[ = \frac{\tan \theta + \cot \theta}{\|x_2\|} \left[ \frac{f(\lambda_1(x))}{\lambda_2(x) - \lambda_1(x)} \right] \frac{\lambda_2(x) - \lambda_1(x)}{\lambda_2(x) - \lambda_1(x)} \delta(\lambda_2(x), \lambda_1(x)), \]

where the third equation follows from the fact \( \lambda_2(x) - \lambda_1(x) = (\tan \theta + \cot \theta) \|x_2\| \). Similarly, we have

\[ \tilde{a} \tan \theta + \tilde{d} \]
\[ = \frac{(\tan \theta + \cot \theta) [f(\lambda_1(x)) - f(\lambda_2(x))]}{\|x_2\|} \frac{1}{\lambda_2(x) - \lambda_1(x)} \left[ \frac{2 \tan^2 \theta + \tan \theta - 1}{\tan^2 \theta} \delta(\lambda_1(x), \lambda_2(x)) + \delta(\lambda_2(x), \lambda_1(x)) \right], \]
\[ \tilde{a} \cot \theta + \tilde{d} \]
\[ = \frac{(\tan \theta + \cot \theta) [f(\lambda_1(x)) - f(\lambda_2(x))] - f'(\lambda_2(x))(\lambda_1(x) - \lambda_2(x))}{\|x_2\|} \frac{1}{\lambda_2(x) - \lambda_1(x)} \delta(\lambda_1(x), \lambda_2(x)), \]
\[ \tilde{a} \tan^3 \theta + \tilde{d} \]
\[ = \frac{(\tan \theta + \cot \theta) [f(\lambda_1(x)) - f(\lambda_2(x))] - [\tan^2 \theta f'(\lambda_2(x))] (\lambda_1(x) - \lambda_2(x))}{\|x_2\|} \frac{1}{\lambda_2(x) - \lambda_1(x)} \delta(\lambda_1(x), \lambda_2(x)) \]
\[ + \frac{\tan \theta + \cot \theta}{\|x_2\|} \left[ \frac{\tan^2 \theta \delta(\lambda_1(x), \lambda_2(x)) + (\tan^2 \theta - 1) \delta(\lambda_2(x), \lambda_1(x))}{\lambda_2(x) - \lambda_1(x)} \right]. \]
Corresponding each coefficient in (18) to (3), we know

\[
\begin{align*}
\alpha_1 &= (\tan^4 \theta - 1)f''(\lambda_1(x))^2, \\
\alpha_2 &= \frac{\tan^2 \theta + \cot^2 \theta}{|x_2 - x_1|^2} \theta(\lambda_2(x), \lambda_1(x))[\frac{2\tan^2 \theta}{\tan^2 \theta + 1}\delta(\lambda_1(x), \lambda_2(x)) + \frac{\tan^2 \theta - 1}{\tan^2 \theta + 1}\theta(\lambda_2(x), \lambda_1(x))], \\
\alpha_3 &= 2\left[ \frac{\tan^2 \theta + \cot^2 \theta}{|x_2 - x_1|^2} \delta(\lambda_2(x), \lambda_1(x)) + (\tan^2 \theta - 1)\theta(\lambda_2(x), \lambda_1(x)) \right] f''(\lambda_1(x)), \\
\alpha_4 &= 2\left( \frac{\tan^2 \theta + 1}{|x_2 - x_1|^2} \delta(\lambda_2(x), \lambda_1(x)) \right) f''(\lambda_2(x)), \\
\alpha_5 &= -2\left( \frac{\tan^2 \theta + 1}{|x_2 - x_1|^2} \delta(\lambda_2(x), \lambda_1(x)) \right) \theta(\lambda_2(x), \lambda_1(x)).
\end{align*}
\]

In view of Lemma 2.1, the condition \( \alpha_1 \geq 0 \) means \( \tan \theta \geq 1 \), \( \alpha_2, \alpha_5 \geq 0 \) is ensured by the convexity of \( f \) (see (14)), \( \alpha_4 \geq 0 \) corresponds to (6), and \( \alpha_3 \geq -2\sqrt{\alpha_1 \alpha_2} \) corresponds to (7). In addition, condition (4) takes the special form (9) and (10), respectively.

**Theorem 2.2** Suppose that \( f : J \to \mathbb{R} \) is second-order continuously differentiable. Then \( f \) is \( L_\theta \)-convex of order 2 on \( S \) if and only if \( \tan \theta \geq 1 \) and \( f \) is convex on \( J \).

**Proof** The necessity is clear from Theorem 2.1. For sufficiency, note that in (11) \( \mu_3 = 0 \) since \( \lambda_2 = \pm 1 \) in this case. Hence, (18) takes the form of

\[
(\tan^4 \theta - 1)f''(\lambda_1(x))^2 \mu_1^2 + 2(\tan^2 \theta + 1)f''(\lambda_1(x))f'''(\lambda_2(x))\mu_1^2 \mu_2^2 \geq 0
\]

for all \( \mu_1 \) and \( \mu_2 \), which is equivalent to verifying

\[
\tan \theta \geq 1 \quad \text{and} \quad f'''(\lambda_1(x))f''(\lambda_2(x)) \geq 0.
\]

This is ensued by the conditions that \( \tan \theta \geq 1 \) and \( f \) is convex on \( J \). Thus, the proof is complete.

If, in particular, \( \theta = 45^\circ \), then (6) and (7) reduce to [12, (21) in Proposition 4.2]; (9) reduces to [12, (22) in Proposition 4.2]. In addition, due to (7), (8) holds automatically in this case. The above results indicate that the \( L_\theta \)-convexity is dependent on the properties of \( f \) and the angle \( \theta \) together.

### 3 Inequalities associated with circular cone

In this section, we establish some inequalities associated with circular cone, which we believe will be useful for further analyzing the properties of \( f_{L_\theta} \) and proving the convergence of interior point methods for optimization problems involved in circular cones.

In [18], the author establishes the following results in the framework of second-order cone. More specifically, for \( x \succeq_{L_{45^\circ}} 0 \) and \( y \succeq_{L_{45^\circ}} 0 \), then

(a) \( \det(e + x)^{1/2} \geq 1 + \det(x)^{1/2} \),
(b) \( \det(x + y) \geq \det(x) + \det(y) \),
(c) \( \det(\alpha x + (1 - \alpha)y) \geq \alpha^2 \det(x) + (1 - \alpha)^2 \det(y), \forall \alpha \in [0, 1] \),
(d) \( \det(e + x + y) \leq \det(e + x)\det(e + y) \).
Let \( x = (x_1, x_2) \in \mathbb{R} \times \mathbb{R}^{n-1} \) possess spectral factorization associated with circular cone given as in (1). Then
(a) \( [\det(e + x)]^{1/2} \geq 1 + \det(x)^{1/2} \) for all \( x \in \mathcal{L}_\theta \);
(b) If \( x \geq \mathcal{L}_\theta y \), then \( \lambda_1(x) \geq \lambda_1(y) \).

Proof (a) Note that \( \det(x) \geq 0 \) and \( \det(e + x) \geq 0 \) since \( x, x + e \in \mathcal{L}_\theta \). Therefore,

\[
[\det(e + x)]^{1/2} \geq 1 + \det(x)^{1/2}
\]

\[
\iff \det(e + x) \geq 1 + 2 \det(x)^{1/2} + \det(x)
\]

\[
\iff \lambda_1(e + x)\lambda_2(e + x) \geq 1 + 2\sqrt{\lambda_1(x)\lambda_2(x)} + \lambda_1(x)\lambda_2(x)
\]

\[
\iff (x_1 + 1 - \|x_2\| \cot \theta)(x_1 + 1 + \|x_2\| \tan \theta) \geq 1 + 2\sqrt{\lambda_1(x)\lambda_2(x)} + \lambda_1(x)\lambda_2(x)
\]

\[
\iff (\lambda_1(x) + 1)(\lambda_2(x) + 1) \geq 1 + 2\sqrt{\lambda_1(x)\lambda_2(x)} + \lambda_1(x)\lambda_2(x)
\]

\[
\iff \lambda_1(x)\lambda_2(x) + \lambda_1(x) + \lambda_2(x) + 1 \geq 1 + 2\sqrt{\lambda_1(x)\lambda_2(x)} + \lambda_1(x)\lambda_2(x)
\]

\[
\iff \lambda_1(x) + \lambda_2(x) \geq 2\sqrt{\lambda_1(x)\lambda_2(x)}
\]

\[
\iff \frac{\lambda_1(x) + \lambda_2(x)}{2} \geq \sqrt{\lambda_1(x)\lambda_2(x)}.
\]

Hence, to prove the desired result, it suffices to show that

\[
\frac{\lambda_1(x) + \lambda_2(x)}{2} \geq \sqrt{\lambda_1(x)\lambda_2(x)},
\]

which is clearly true by the arithmetic mean-geometric mean (AM-GM) inequality.

(b) Since \( x - y \in \mathcal{L}_\theta \), we know

\[
x_1 - y_1 \geq \|x_2 - y_2\| \cot \theta \geq \left[ \|x_2\| - \|y_2\| \right] \cot \theta,
\]

i.e., \( \lambda_1(x) = x_1 - \|x_2\| \cot \theta \geq y_1 - \|y_2\| \cot \theta = \lambda_1(y) \).

\[\square\]

Theorem 3.2 Let \( x = (x_1, x_2) \in \mathbb{R} \times \mathbb{R}^{n-1} \) possess spectral factorization associated with circular cone given as in (1). Then the following hold.
(a) For all \( x, y \in \mathcal{L}_\theta \),

\[
\det(x + y) \geq \det(x) + \det(y) + (\|x_2\|^2 + \|y_2\|^2) \csc^2 \theta - (x_1^2 + y_1^2) \sec^2 \theta.
\]

In particular, when \( \theta \in (0, 45^\circ] \), we have

\[
\det(x + y) \geq \det(x) + \det(y).
\]

(19)
(b) For all \(x, y \in L_\theta\) and \(\alpha \in [0, 1]\),
\[
\det(ax + (1 - \alpha)y) \\
\geq \alpha^2 \det(x) + (1 - \alpha)^2 \det(y) + (\alpha^2 \|x_2\|^2 + (1 - \alpha)^2 \|y_2\|^2) \csc^2 \theta \\
- (\alpha^2 x_1^2 + (1 - \alpha)^2 y_1^2) \sec^2 \theta.
\]

In particular, when \(\theta \in (0, 45^\circ]\), we have
\[
\det(ax + (1 - \alpha)y) \geq \alpha^2 \det(x) + (1 - \alpha)^2 \det(y).
\]

(c) If \(x, y \in L_\theta\) and \(\theta \in [45^\circ, 90^\circ)\), then
\[
\det(e + x + y) \leq \det(e + x) \det(e + y).
\]

(d) If \(x \geq L_\theta, y \geq L_\theta, 0, \) and \(\theta \in (0, 45^\circ]\), then
\[
\lambda_2(x) \geq \lambda_2(y), \quad \det(x) \geq \det(y), \quad \text{and} \quad \text{tr}(x) \geq \text{tr}(y).
\]

**Proof** (a) Notice that
\[
det(x + y) \\
= \lambda_1(x + y) \cdot \lambda_2(x + y) \\
= (x_1 + y_1 - \|x_2 + y_2\| \cot \theta)(x_1 + y_1 + \|x_2 + y_2\| \tan \theta) \\
= (x_1 + y_1)^2 + (x_1 + y_1)\|x_2 + y_2\| \tan \theta - (x_1 + y_1)\|x_2 + y_2\| \cot \theta - \|x_2 + y_2\|^2
\]
and
\[
det(x) + det(y) \\
= \lambda_1(x)\lambda_2(x) + \lambda_1(y)\lambda_2(y) \\
= (x_1 - \|x_2\| \cot \theta)(x_1 + \|x_2\| \tan \theta) + (y_1 - \|y_2\| \cot \theta)(y_1 + \|y_2\| \tan \theta) \\
= x_1^2 + x_1\|x_2\| \tan \theta - x_1\|x_2\| \cot \theta - \|x_2\|^2 + y_1^2 + y_1\|y_2\| \tan \theta - y_1\|y_2\| \cot \theta - \|y_2\|^2 \\
= x_1^2 + y_1^2 + x_1\|x_2\| \tan \theta + y_1\|y_2\| \tan \theta - x_1\|x_2\| \cot \theta - y_1\|y_2\| \cot \theta - \|x_2\|^2 - \|y_2\|^2.
\]

Then we have
\[
det(x + y) - det(x) - det(y) \\
= 2x_1y_1 - 2x_2^2y_2 + (x_1\|x_2 + y_2\| + y_1\|x_2 + y_2\| - x_1\|x_2\| - y_1\|y_2\|) \tan \theta \\
- (x_1\|x_2 + y_2\| + y_1\|x_2 + y_2\| - x_1\|x_2\| - y_1\|y_2\|) \cot \theta.
\]

Using \(x, y \in L_\theta\) (and hence \(x + y \in L_\theta\)) gives
\[
x_1 \tan \theta \geq \|x_2\|, \quad -x_1 \tan \theta \leq -\|x_2\|, \quad x_1 \geq \|x_2\| \cot \theta, \quad -x_1 \leq -\|x_2\| \cot \theta, \\
-(x_1 + y_1) \leq -\|x_2 + y_2\| \cot \theta.
\]
Thus,

\[
\begin{align*}
\det(x + y) - \det(x) - \det(y) & \geq 2x_1y_1 - 2x_1^2y_2 + \|x_2\|\|x_2 + y_2\| + \|y_2\|\|x_2 + y_2\| - x_1^2\tan^2\theta - y_1^2\tan^2\theta \\
& \quad - x_1(x_1 + y_1) - y_1(x_1 + y_1) + \|x_2\|^2\cot^2\theta + \|y_2\|^2\cot^2\theta \\
& = 2x_1y_1 - 2x_1^2y_2 + \|x_2 + y_2\|\left(\|x_2\| + \|y_2\|\right) - (x_1^2 + y_1^2)\tan^2\theta \\
& \quad - (x_1 + y_1)^2 + (\|x_2\|^2 + \|y_2\|^2)\cot^2\theta \\
& \geq \|x_2 + y_2\|^2 - (x_1^2 + y_1^2)\tan^2\theta - x_1^2 - y_1^2 - 2x_1^2y_2 + \left(\|x_2\|^2 + \|y_2\|^2\right)\cot^2\theta \\
& = \|x_2\|^2 + \|y_2\|^2 - (x_1^2 + y_1^2)\tan^2\theta - x_1^2 - y_1^2 + \left(\|x_2\|^2 + \|y_2\|^2\right)\cot^2\theta \\
& = \left(\|x_2\|^2 + \|y_2\|^2\right)(1 + \cot^2\theta) - (x_1^2 + y_1^2)(1 + \tan^2\theta) \\
& = \left(\|x_2\|^2 + \|y_2\|^2\right)\csc^2\theta - (x_1^2 + y_1^2)\sec^2\theta,
\end{align*}
\]

which is the desired result.

When \(\theta \in (0, 45^\circ]\), we know \(\tan\theta \leq \cot\theta\). Since \(x, y \in \mathcal{L}_\theta\), i.e., \(x_1 \geq \|x_2\|\cot\theta\) and \(y_1 \geq \|y_2\|\cot\theta\), there exist \(a, b \geq 0\) such that \(x_1 = \|x_2\|\cot\theta + a\) and \(y_1 = \|y_2\|\cot\theta + b\). Hence,

\[
\begin{align*}
\det(x + y) - \det(x) - \det(y) & = 2x_1y_1 - 2x_1^2y_2 + (x_1\|x_2 + y_2\| + y_1\|x_2 + y_2\| - x_1\|x_2\| - y_1\|y_2\|)\tan\theta \\
& \quad - (x_1\|x_2 + y_2\| + y_1\|x_2 + y_2\| - x_1\|x_2\| - y_1\|y_2\|)\cot\theta \\
& \quad + \|x_2 + y_2\|\left(\|x_2\| + \|y_2\|\right)\cot^2\theta \\
& \quad + a\cot\theta\left(\|y_2\| + \|x_2 + y_2\|\right) + a\tan\theta\left(\|y_2\|\cot^2\theta + x_2 + y_2\| - \|x_2\|\right) \\
& \quad + b\cot\theta\left(\|y_2\| + \|x_2 - \|x_2 + y_2\|\right) + b\tan\theta\left(\|x_2\|\cot^2\theta + x_2 + y_2\| - \|y_2\|\right) \\
& \geq 0,
\end{align*}
\]

where the last step is due to \(\|x_2\| + \|y_2\| \geq \|x_2 + y_2\|,\|x_2\|\cot^2\theta + \|x_2 + y_2\| - \|y_2\| \geq \|x_2\| + \|x_2 + y_2\| - \|y_2\| \geq 0\), and \(\|y_2\|\cot^2\theta + \|x_2 + y_2\| - \|x_2\| \geq \|y_2\| + \|x_2 + y_2\| - \|x_2\| \geq 0\) since \(\cot\theta \geq 1\), due to \(\theta \in (0, 45^\circ]\).

(b) The result follows from the fact that \(\det(yx) = y^2\det(x)\) for all \(y \geq 0\).

(c) Since \(\theta \in [45^\circ, 90^\circ]\), \(\cot\theta \leq 1\). For \(x, y \in \mathcal{L}_\theta\), there exist two nonnegative scalars \(a, b \geq 0\) such that \(x_1 = \|x_2\|\cot\theta + a\) and \(y_1 = \|y_2\|\cot\theta + b\). This implies

\[
\begin{align*}
\det(e + x) & = (x_1 + 1 - \|x_2\|\cot\theta)(x_1 + 1 + \|x_2\|\tan\theta) \\
& = (a + 1)(\cot\theta + \tan\theta)\|x_2\| + (a + 1)^2, \\
\det(e + y) & = (y_1 + 1 - \|y_2\|\cot\theta)(y_1 + 1 + \|y_2\|\tan\theta) \\
& = (b + 1)(\cot\theta + \tan\theta)\|y_2\| + (b + 1)^2.
\end{align*}
\]
Thus, we obtain

$$\det(e + x) \det(e + y)$$

$$= (a + 1)(b + 1)(\cot \theta + \tan \theta)^2 \|x_2\| \|y_2\| + (a + 1)(b + 1)^2(\cot \theta + \tan \theta)\|x_2\|$$

$$+ (a + 1)^2(b + 1)(\cot \theta + \tan \theta)\|y_2\| + (a + 1)^2(b + 1)^2. \tag{22}$$

On the other hand,

$$\det(e + x + y)$$

$$= (x_1 + y_1 + 1 - \|x_2 + y_2\| \cot \theta)(x_1 + y_1 + 1 + \|x_2 + y_2\| \tan \theta)$$

$$= \left(\|x_2\| + \|y_2\| - \|x_2 + y_2\| \cot \theta + (a + b + 1)\right)$$

$$\times \left(\|x_2\| + \|y_2\| \cot \theta + \|x_2 + y_2\| \tan \theta + (a + b + 1)\right)$$

$$= \left(\|x_2\| + \|y_2\| - \|x_2 + y_2\| \right)\left(\|x_2\| + \|y_2\| \right) \cot^2 \theta$$

$$+ \left(\|x_2\| + \|y_2\| - \|x_2 + y_2\| \right)\left(\|x_2\| + \|y_2\| \right) \cot \theta$$

$$+ (a + b + 1)\|x_2\| + \|y_2\| \tan \theta + (a + b + 1)^2$$

$$\leq 2\cot^2 \theta \|x_2\| \|y_2\| + 2(a + b + 1) \cot \theta \|x_2\| + 2(a + b + 1)^2 \cot \theta \|y_2\| + (a + b + 1)^2$$

$$+ \left[\|x_2\|^2 + \|y_2\|^2 \right] \cot^2 \theta + \left(1 - \cot^2 \theta \right)\|x_2\| + \|y_2\|^2$$

$$+ (a + b + 1)(\tan \theta - \cot \theta)\|x_2\| + \|y_2\|^2$$

$$\leq 2\cot^2 \theta \|x_2\| \|y_2\| + 2(a + b + 1) \cot \theta \|x_2\| + 2(a + b + 1)^2 \cot \theta \|y_2\| + (a + b + 1)^2$$

$$+ \left[\|x_2\|^2 + \|y_2\|^2 \right] \cot^2 \theta + \left(1 - \cot^2 \theta \right)\|x_2\| + \|y_2\|^2$$

$$+ (a + b + 1)^2 + (1 - \cot^2 \theta)\|x_2\| + \|y_2\|^2$$

$$= 2\cot^2 \theta \|x_2\| \|y_2\| + (a + b + 1)(\cot \theta + \tan \theta)\|x_2\| + (a + b + 1)(\cot \theta + \tan \theta)\|y_2\|$$

$$+ (a + b + 1)^2 + (1 - \cot^2 \theta)\|x_2\| + \|y_2\|^2$$

$$= 4\|x_2\| \|y_2\| + (a + b + 1)(\cot \theta + \tan \theta)\|x_2\| + (a + b + 1)(\cot \theta + \tan \theta)\|y_2\|$$

$$+ (a + b + 1)^2. \tag{23}$$

Note that $(a + 1)(b + 1)(\cot \theta + \tan \theta)^2 \geq (\cot \theta + \tan \theta)^2 \geq 4$ and

$$(a + 1)(b + 1)^2 \geq a + b + 1,$$

$$(a + 1)^2(b + 1) \geq a + b + 1,$$

$$(a + 1)^2(b + 1)^2 \geq (a + b + 1)^2.$$
which means
\[
\lambda_2(x) = x_1 + \|x_2\| \tan \theta \geq y_1 + \|y_2\| \tan \theta = \lambda_2(y).
\]

This together with the fact \(\lambda_i(x) \geq \lambda_i(y)\) by Part (b) in Theorem 3.1 and \(\lambda_i(x), \lambda_i(y) \geq 0\) for \(i = 1, 2\) (due to \(x, y \in E\)) further yields
\[
det(x) = \lambda_1(x) \lambda_2(x) \geq \lambda_1(y) \lambda_2(y) = det(y).
\]

Meanwhile, we obtain
\[
tr(x) = \lambda_1(x) + \lambda_2(x) \geq \lambda_1(y) + \lambda_2(y) = tr(y).
\]

Here are some remarks for Theorem 3.2.
(i) Inequality (19) fails when \(\theta \in (45^\circ, 90^\circ)\). For example, let \(x = (1, 3, 4)\), \(y = (1, -3, -4)\), and \(\cot \theta = 0.1\). Then \(det(x) = det(y) = 51/2\) and \(det(x + y) = 4\), which says \(det(x + y) = 4 < 51 = det(x) + det(y)\).
(ii) Inequality (20) fails when \(\theta \in (0, 45^\circ)\). For example, let \(x = (3/10, 1/10)\), \(y = (3/10, -1/10)\), and \(\cot \theta = 2\). Then \(det(e + x + y) = (1.6)^2 > (1.485)^2 = det(e + x) det(e + y)\).
(iii) Inequality (21) fails when \(\theta \in (45^\circ, 90^\circ)\). For example, for \(x = (1, 1, 1)\), \(y = (1, 2)\), and \(\cot \theta = 0.1\). Then \(x \succeq_{\angle} y, \lambda_2(x) = 11.1 < 21 = \lambda_2(y)\), \(det(x) = (1.1 - 0.1)(1.1 + 10) = 11.1 < 16.8 = (1 - 0.2)(1 + 20) = det(y)\), and \(tr(x) = 12.1 < 21.8 = tr(y)\).

Next, let us move from inequalities to equalities. In particular, we focus on two identities in the framework of second-order cone as below
\[
tr(x + y) = tr(x) + tr(y) \quad \text{and} \quad det(y \cdot x) = y^2 det(x), \quad \forall y \in \mathbb{R}.
\]  

But these two identities fail to hold in the circular cone setting no matter what value of the angle is chosen. In fact, in the second-order cone case,
\[
tr(x) = 2x_1 \quad \text{and} \quad det(x) = x_1^2 - \|x_2\|^2.
\]

Hence, (24) holds trivially. For the circular cone setting, we have
\[
tr(x) = 2x_1 + \|x_2\|(\tan \theta - \cot \theta) \quad \text{and} \quad det(x) = (x_1 - \|x_2\| \cot \theta)(x_1 + \|x_2\| \tan \theta).
\]
Thus, \(tr(x)\) is not linear any more, \(i.e., tr(x + y) \neq tr(x) + tr(y)\); \(e.g.,\) for \(x = (1, 2)\) and \(y = (1, -2)\), and \(\cot \theta = 1/2\) (or \(\cot \theta = 2\)). Then
\[
tr(x + y) = 4 \neq 10 = tr(x) + tr(y) \quad \text{(or} \quad tr(x + y) = 4 \neq -2 = tr(x) + tr(y)).
\]

In addition, \(det(y \cdot x) = y^2 det(x)\) holds as \(y \geq 0\) but not true as \(y < 0\); \(e.g.,\) for \(x = (3, 4)\), \(y = -2\), and \(\cot \theta = 1/2\) (or \(\cot \theta = 2\)), then
\[
det(-2x) = -100 \neq 44 = (-2)^2 det(x) \quad \text{(or} \quad det(-2x) = 44 \neq -100 = (-2)^2 det(x)).
\]
The precise relationship between \( \text{tr}(x + y) \) and \( \text{tr}(x) + \text{tr}(y) \) is provided as below.

**Theorem 3.3**

\[
\text{tr}(x + y) \begin{cases} 
\geq \text{tr}(x) + \text{tr}(y) & \text{as } \theta \in (0, 45^\circ], \\
\leq \text{tr}(x) + \text{tr}(y) & \text{as } \theta \in [45^\circ, 90^\circ]).
\end{cases}
\]

**Proof** The result follows from the fact that

\[
\text{tr}(x + y) - \text{tr}(x) - \text{tr}(y) = \left[\|x_2\| + \|y_2\| - \|x_2 + y_2\|\right](\cot \theta - \tan \theta).
\]

Note that \( \text{tr}(x) \) is positively homogeneous, i.e., \( \text{tr}(\gamma x) = \gamma \text{tr}(x) \) for all \( \gamma \geq 0 \). This together with Theorem 3.3 yields the following result.

**Corollary 3.1** The trace \( \text{tr}(x) \) is concave as \( \theta \in (0, 45^\circ] \) and is convex as \( \theta \in [45^\circ, 90^\circ) \).

These results further indicate that the angle plays an essential role for a circular cone. As in symmetric cone optimization, we believe that these inequalities about \( \det(x) \) and \( \text{tr}(x) \) are key ingredients in penalty and barrier functions which can be adapted in designing barrier and penalty algorithms (including interior point algorithm) for circular cone optimization. This merits our further research.
